Effect of yoga asanas and pranayama on selected physiological variables of sedentary adolescents

Badshah Ghosh

Abstract
The purpose of the study was to investigate the effect of asanas and pranayama on selected physiological variables of the adolescents. The subjects for this study were thirty male students randomly selected from Vivek Jyoti Vidya Mandir, Panskura, Purba Medinipur, West Bengal. The age of the subjects ranged between 14 – 17 years. The subjects were equally divided into three groups namely two experimental and one control group. The treatments to the experimental groups were assigned randomly; one for Asanas and another for Pranayama and the third group served as control group. The treatment schedule was prepared for twelve weeks. The experimental treatments were employed for 45 minutes a day in five days a week for twelve weeks duration. Pre and post-test data of all the subjects from three groups were collected before and after the experimental treatment period of 12 weeks. The selected variables were Peak Heart Rate and Vital capacity. The data was analyzed by employing analysis of covariance at the 0.05 level of significance. The result of the study indicates that practice of both Asanas and Pranayama had significant effect on Peak Heart Rate and Vital capacity of the subjects.

Keywords: Asanas, Pranayama, Peak heart Rate, Vital Capacity.

1. Introduction
The classical techniques of Yoga date back more than 5,000 years. In ancient times, the desire for greater personal freedom, health and long life, and heightened self-understanding gave birth to this system of physical and mental exercise which has since spread throughout the world. The word Yoga means “to join or yoke together,” and it brings the body and mind together into one harmonious experience.

Asanas are the static posture accredited with values of promoting physical fitness. Element of exertion with characteristics other physical exercises is eliminated in the system of asanas. Asanas have been classified into meditative and cultural poses. The aim of cultural poses is to produce a state of physiological balance in the human body so that it can posses the best organic vigor. Yogic Asanas help in the prevention and cure of many physical diseases, especially those of the digestive tract by regulating the secretion of various duct and ductless gland. Apart from all these yoga is an extremely economic practice.

Pranayama is an art and has techniques to make the respiratory organs to move and expand intentionally, rhythmically and intensively. It consists of long, sustained subtle flow of inhalation, exhalation and retention of breath. Puraka stimulates the system, Rechaka throws out vitiated air and toxins; Kumbhaka distributes the energy throughout the body. The movements include horizontal of the lungs and the ribcage. This disciplined breathing helps the mind to concentrate and enables the practitioner to attain robust health and longevity (Gore and Gharote, 1986) [6].

The word Kapalbhati consist of two words, kapal meaning skull (here, skull includes all the organs under the skull too) and bhati means shining, illuminating. Bhati is light or splendor but it also means perception and knowledge. The scientific word published on this practice is related to the composition of alveolar air, breath holding time and urinary output as influenced by this practice. Kapalbhati is a technique of incessant abdominal breathing included in the practices of yoga. The Kapalbhati impulsive force is applied with Greater Magnitude while the stroke time is very small (Ghosh and Choudhary, 2014) [4]. Many studies have been done to highlight the positive effect yoga; this study was an attempt to find out the effect of certain yogic asanas and pranayam on some physiological variable of sedentary youths.
1.1. Objective of the Study
The purpose of the study was to find out the effect of yoga asanas and pranayama on certain physiological variables of sedentary youths studying in public school.

1.2. Hypothesis
It was hypothesized that there would be significant changes in the selected physiological variables of the subject who were sedentary in nature, after the training of twelve weeks.

2. Methodology
The purpose of the study was to investigate the effect of asanas and pranayama on selected physiological variables of the adolescents. The investigator was more interested to find the effect of asanas and pranayama particularly on the sedentary adolescents who had not been taking part in any other physical activity.

2.1. Subjects
Thirty sedentary adolescents selected from Vivek Jyoti Vidya Mandir, Panskura, Purba Medinipur, West Bengal. The subjects were selected from a private model school as because it is easy to find sedentary children there. The age of the subjects ranged between 14 – 17 years. The only purpose of selecting subjects over 14 years was to insure that the selected subjects had attained puberty. The subjects were divided into three equal groups and the distribution was done randomly. Two experimental groups were (N=10 each) namely Asanas (G1) and Kapalbhati (G2) and the third group served as control group.

2.2. Treatment
The training schedule was prepared for twelve weeks. The practice schedule included 12 asanas for asanas group initiated and ended with Surya Namaskar asanas and the only one pranayama chosen for the study was Kapalbhati for the pranayama group. However, the pranayama group performed Anuloma- Viloma at the beginning of the Kapalbhati and also in between for the relaxation between each sets. Only those asanas were selected who plays direct role on the cardio respiratory system. The experimental treatments were employed for 45 minutes a day in five days a week for the period of twelve weeks. The third group served as control groups (G3).

2.3. Collection of Data
Cardio respiratory variables chosen for the study were Peak Heart Rate and Vital Capacity. Standard test and measurement procedures were adopted to collect data for the study. The Vital capacity was measured with the help of dry spirometer. The Peak heart rate was measured after putting the subjects at sub maximal work load. To assess the sub maximal work load a pilot study was done for find out the height of the bench and the number of steps per minute. The subjects were asked to perform step up test to assess the Peak heart rate. The Pre and post test data of all the subjects from three groups were collected before and after the experimental period of twelve weeks. The data was analyzed by employing analysis of covariance at the 0.05 level of significance.

3. Finding
In order to identify the significant differences among three groups on selected variables, collected pre and post training were analyzed using the analysis of covariance. The findings of the study have been presented with the help of following tables.

Fig 1: Mean Value of Asana, Pranayama and Control Groups with respect to Peak Hearts Rate
The table-1 of analysis of covariance for Peak heart rate of asanas and kapalbhati and control group indicated in significant F-ratio of 2.93 and 1.650 for the initial and final test of means respectively. However, the F-ratio for the adjusted final test mean reveal a value of 5.22 which was significant as it was greater than the F-value of 3.59 required for significant at 0.05 level. This indicates that there was significant difference from the adjusted final means of Asanas, Kapalbhati and control groups in the Peak heart rate.

Table-2: Paired Adjusted Final Mean and Difference between Means of Three Different Groups of Peak Heart Rate

<td>154.78</td>
<td>158.8</td>
</tr>
</tbody>
</table>

Table-2 indicates that the difference between the paired adjusted final means of Asanas, Kapalbhati and control groups in Peak heart rate indicated significant value of 3.77* and 4.02* which emphasis greater mean gain observed for Asanas, Kapalbhati as compared to the control group.

</table>

Table-4 indicates that the difference between the paired adjusted final means of Asanas, Kapalbhati and control group in vital capacity indicated significant value of 0.08 and 0.07* which emphasis greater mean gain observed for Asanas and Kapalbhati group as compared to the control group.
4. Conclusion
On the basis of result of the study following conclusions are drawn:
1. Both Asanas and Kapalbhati Pranayama had significant contributing role over the Peak Heart rate of subjects as a result of twelve weeks yogic training.
2. It can be said that the effect of twelve weeks practice of Asanas and Kapalbhati Pranayama was significant enough to bring about the change in the vital capacity.

5. Recommendation
The twenty first century started as the era of technology then with the advancement new names added to the list like remote era, button era but people have started calling this era as the era of touch. But the advancement of technology the people have started alienating from physical labor and started leading more and more sedentary life style. This life style leads to hypokinetic disease. It has been advised by all the yoga experts to practice yoga asanas and pranayama for healthy and disease free life. The practice of yoga can be done at any time of the day and at any place and people get great benefit from this and the result of the study also suggest the same.

6. Acknowledgement
The author wish to thank the principal of the Vivek Jyoti Vidya Mandir, Panskura, Purba Medinipur, West Bengal, for sparing the students for one hour at the Panskura Banamali College for the training and data collection. The scholar would also extend his thanks to physical education teacher of that school for his willingness and wholehearted cooperation as well as for the pain he took to escort the students from the school to the center of training. The researcher is also wish to give heartily thanks to principal of Panskura Banamali College, for providing the permission to conduct the study at the college and also to the students of the scholar for their generous help.
